    delta[2*i+1] += delta[i];
    delta[i] = 0;
}
```

2.4. Union Find. This data structure is used in varoius algorithms, for example Kruskals algorithm for finding a Minimal Spanning Tree in a weighted graph. Also it can be used for backward simulation of dividing a set.

```
private class Node {
 Node parent:
 int h;
  public Node() {
   parent = this;
   h = 0:
  public Node find() {
   if(parent != this) parent = parent.find();
    return parent;
static void union(Node x, Node y) {
 Node xR = x.find(), yR = y.find();
 if(xR == yR) return;
 if(xR.h > yR.h)
   yR.parent = xR;
  else {
   if(yR.h == xR.h) yR.h++;
   xR.parent = yR;
 }
```

2.5. Monotone Queue. Used in sliding window algorithms where one would like to find the minimum in each interval of a given length. Amortized $\mathcal{O}(n)$ to find min in each of these intervals in an array of length n. Can easily be used to find the maximum as well.

```
private static class MinMonQue {
   LinkedList<Integer> que = new LinkedList<>();
   public void add(int i) {
      while(!que.isEmpty() && que.getFirst() > i)
            que.removeFirst();
      que.addFirst(i);
   }
   public int last() {
      return que.getLast();
   }
   public void remove(int i) {
      if(que.getLast() == i) que.removeLast();
}
```

```
}
}
```

2.6. **Treap.** Treap is a binary search tree that uses randomization to balance itself. It's easy to implement, and gives you access to the internal structures of a binary tree, which can be used to find the k'th element for example. Because of the randomness, the average height is about a factor 4 of a prefectly balanced tree.

3

```
class Treap{
 int sz;
 int v;
 double v;
 Treap L, R;
 static int sz(Treap t) {
   if(t == null) return 0;
   return t.sz;
 static void update(Treap t) {
   if(t == null) return;
   t.sz = sz(t.L) + sz(t.R) + 1;

   if (t.R == null) return t;
    return Right(t.R);
 }
}
               3. Graph Algorithms
```

3.1. Djikstras algorithm. Finds the shortest distance be-

```
tween two Nodes in a weighted graph in \mathcal{O}(|E|\log|V|) time.
//Requires java.util.LinkedList and java.util.TreeSet
private static class Node implements Comparable<Node>{ minimal vertex-cover, which as we all know is the complement
  LinkedList<Edge> edges = new LinkedList<>();
  int w:
  int id:
  public Node(int id) {
    w = Integer.MAX_VALUE;
    this.id = id;
```

```
public int compareTo(Node n) {
    if(w != n.w) return w - n.w;
    return id - n.id:
  //Asumes all nodes have weight MAXINT.
  public int djikstra(Node x) {
    this.w = 0;
    TreeSet<Node> set = new TreeSet<>();
    set.add(this):
    while(!set.isEmpty()) {
      Node curr = set.pollFirst();
      if(x == curr) return x.w;
      for(Edge e: curr.edges) {
        Node other = e.u == curr? e.v : e.u;
        if(other.w > e.cost + curr.w) {
          set.remove(other);
          other.w = e.cost + curr.w:
          set.add(other);
        }
      }
    }
    return -1;
}
private static class Edge {
  Node u,v;
  int cost:
  public Edge(Node u, Node v, int c) {
    this.u = u; this.v = v;
    cost = c;
}
```

3.2. Bipartite Graphs. The Hopcroft-Karp algorithm finds the maximal matching in a bipartite graph. Also, this matching can together with Könings theorem be used to construct a of a maximum independent set. Runs in $\mathcal{O}(|E|\sqrt{|V|})$.

```
import java.util.*;
class Node {
  int id:
 LinkedList<Node> ch = new LinkedList<>();
  public Node(int id) {
    this.id = id:
```

```
}
                                                           private boolean dfs(Node u) {
                                                                                                                        for(Node y: x.ch) {
                                                             for(Node v: u.ch) if(distp(v) == Dist[u.id] + 1) {
                                                                                                                         if(y.id == nono || Z[y.id]) continue;
                                                               if(Pair[v.id] == -1 || dfs(U[Pair[v.id]])) {
public class BiGraph {
                                                                                                                          Z[y.id] = true;

```

```
else
      hi = mid-1;
  int newL = lo;
  P[i] = M[newL-1];
  M[newL] = i;
  if (newL > L)
    L = newL;
int[] S = new int[L];
int k = M[L];
for (int i = L-1; i >= 0; i--) {
  S[i] = k; //or X[k]
  k = P[k];
}
return L: // or S
```

4.2. String functions. The z-function computes the longest common prefix of t and t[i:] for each i in $\mathcal{O}(|t|)$. The boarder function computes the longest common proper (smaller than whole string) prefix and suffix of string t[:i].

```
def zfun(t):
    z = [0]*len(t)
    n = len(t)
    l, r = (0,0)
    for i in range(1,n):
        if i < r:
            z[i] = min(z[i-l], r-i+1)
        while z[i] + i < n and t[i+z[i]] == t[z[i]]:
            z[i]+=1
        if i + z[i] - 1 > r:
            l = i
            r = i + z[i] - 1
    return z
def matches(t, p):
    s = p + '#' + t
    return filter(lambda x: x[1] == len(p),
            enumerate(zfun(s)))
def boarders(s):
    b = [0]*len(s)
```

```
for i in range(1, len(s)):
    k = b[i-1]
    while k>0 and s[k] != s[i]:
        k = b[k-1]
    if s[k] == s[i]:
        b[i] = k+1
return b
                   5. Etc.
```

5.1. System of Equations. Solves the system of equations 5.2. Convex Hull. From a collection of points in the plane Ax = b by Gaussian elimination. This can for example be used to determine the expected value of each node in a markov chain. Runns in $\mathcal{O}(N^3)$.

```
//Computes A^{-1} * b
static double[] solve(double[][] A, double[] b) {
 int N = b.length;
 // Gaussian elimination with partial pivoting
  for (int i = 0; i < N; i++) {
   // find pivot row and swap
   int max = i;
    for (int j = i + 1; j < N; j++)
     if (Math.abs(A[j][i]) > Math.abs(A[max][i]))
        max = i;
    double[] tmp = A[i];
    A[i] = A[max];
    A[max] = tmp;
    double tmp2 = b[i];
    b[i] = b[max];
    b[max] = tmp2;
   // A doesn't have full rank
    if (Math.abs(A[i][i])<0.00001) return null:</pre>
   // pivot within b
    for (int j = i + 1; j < N; j++)
     b[j] = b[i] * A[j][i] / A[i][i];
    // pivot within A
    for (int j = i + 1; j < N; j++) {
      double m = A[i][i] / A[i][i];
      for (int k = i+1; k < N; k++)
       A[j][k] -= A[i][k] * m;
      A[j][i] = 0.0;
 }
 // back substitution
```

```
double[] x = new double[N];
for (int j = N - 1; j >= 0; j--) {
 double t = 0.0:
 for (int k = j + 1; k < N; k++)
   t += A[i][k] * x[k];
 x[i] = (b[i] - t) / A[i][i];
return x;
```

the convex hull is often used to compute the largest distance or the area covered, or the length of a rope that encloses the points. It can be found in $\mathcal{O}(N \log N)$ time by sorting the points on angle and the sweeping over all of them.

```

5.3. Number Theory.
                                                              s.append(r[i]%10)
                                                                                                                              if(adj[a+fst][b+fst] == 0)
```

}

7. Coordinate Geometry

7.1. **Area of a nonintersecting polygon.** The signed area of a polygon with n vertices is given by

$$A = \frac{1}{2} \sum_{i=0}^{n-1} (x_i y_{i+1} - x_{i+1} y_i)$$

7.2. **Intersection of two lines.** Two lines defined by

$$a_1x + b_1y + c_1 = 0$$
$$a_2x + b_2y + c_2 = 0$$

Intersects in the point

$$P = (\frac{b_1c_2 - b_2c_1}{w}, \frac{a_2c_1 - a_1c_2}{w}),$$

where $w = a_1b_2 - a_2b_1$. If w = 0 the lines are parallell.

7.3. Distance between line segment and point. Given a linesegment between point P, Q, the distance D to point R is

```
given by: \begin{split} &a = Q_y - P_y \\ &b = Q_x - P_x \\ &c = P_x Q_y - P_y Q_x \\ &R_P = (\frac{b(bR_x - aR_y) - ac}{a^2 + b^2}, \frac{a(aR_y - bR_x) - bc}{a^2 + b^2}) \\ &D = \begin{cases} \frac{|aR_x + bR_y + c|}{\sqrt{a^2 + b^2}} & \text{if } (R_{P_x} - P_x)(R_{P_x} - Q_x) < 0, \\ \min |P - R|, |Q - R| & \text{otherwise} \end{cases} \end{split}
```

7.4. **Picks theorem.** Find the amount of internal integer coordinates i inside a polygon with picks theorem $A = \frac{b}{2} + i - 1$, where A is the area of the polygon and b is the amount of coordinates on the boundary.

```
7.5. Implementations.
```

import math

```
# Distance between two points
def dist(p, q):
   return math.hypot(p[0]-q[0], p[1] - q[1])
```

```
# given that a != 0 or b != 0
def distl(l, p):
    return (abs(l[0]*p[0] + l[1]*p[1] + l[2])
    /math.hypot(l[0], l[1]))
```

intersects two lines.
