                 2. Data Structures
                                                          ST root = new ST():
                                                                                                                    init():
2.1. Binary Indexed Tree. Also called a fenwick tree.
```

Builds in  $\mathcal{O}(n \log n)$  from an array. Querry sum from 0 to i in  $\mathcal{O}(\log n)$  and updates an element in  $\mathcal{O}(\log n)$ .

```
private static class BIT {
 long[] data;
```

root.li = lN.li: root.ri = rN.ri:

root.sum = lN.sum + rN.sum; //max/min root.lN = lN: root.rN = rN;

static int getSum(ST root, int l, int r) {//max/min return getSum(root.lN.l.r) + getSum(root.rN.l.r); static int update(ST root, int i, int val) { if(root.li==root.ri && i == root.li) { diff = val-root.sum; //max/min int mid = (root.li + root.ri) / 2; if (i <= mid) diff = update(root.lN, i, val);</pre> else diff = update(root.rN, i, val); root.sum+=diff; //ask other child return diff; //and compute max/min

2.3. Lazy Segment Tree. More general implementation of a segment tree where its possible to increase whole segments by some diff, with lazy propagation. Implemented with arrays instead of nodes, which probably has less overhead to write

```
private int[] lo. hi. sum. delta:
public LazySegmentTree(int n) {
public int sum(int a, int b) {
  return sum(1, a, b);
private int sum(int i, int a, int b) {
```

```
if(b < lo[i] || a > hi[i]) return 0;
  if(a <= lo[i] && hi[i] <= b) return sum(i);</pre>
  prop(i):
  int l = sum(2*i, a, b);
  int r = sum(2*i+1, a, b);
  update(i);
  return l + r;
public void inc(int a, int b, int v) {
  inc(1, a, b, v);
private void inc(int i, int a, int b, int v) {
  if(b < lo[i] || a > hi[i]) return;
  if(a <= lo[i] && hi[i] <= b) {</pre>
    delta[i] += v;
    return:
  prop(i);
  inc(2*i, a, b, v);
  inc(2*i+1, a, b, v);
  update(i);
private void init() {
  init(1, 0, n-1, new int[n]);
private void init(int i, int a, int b, int[] v) {
  lo[i] = a;
  hi[i] = b;
  if(a == b) {
    sum[i] = v[a];
    return;
  int m = (a+b)/2;
  init(2*i, a, m, v);
  init(2*i+1, m+1, b, v);
  update(i):
private void update(int i) {
  sum[i] = sum(2*i) + sum(2*i+1);
private int range(int i) {
  return hi[i] - lo[i] + 1;
```

```
private int sum(int i) {
  return sum[i] + range(i)*delta[i];
}
private void prop(int i) {
  delta[2*i] += delta[i];
  delta[2*i+1] += delta[i];
  delta[i] = 0;
}
```

2.4. **Union Find.** This data structure is used in varoius algorithms, for example Kruskals algorithm for finding a Minimal Spanning Tree in a weighted graph. Also it can be used for backward simulation of dividing a set.

```
private class Node {
 Node parent;
  int h;
  public Node() {
    parent = this;
    h = 0:
  public Node find() {
   if(parent != this) parent = parent.find();
    return parent;
static void union(Node x, Node v) {
 Node xR = x.find(), yR = y.find();
 if(xR == yR) return;
 if(xR.h > yR.h)
   yR.parent = xR;
  else {
   if(vR.h == xR.h) vR.h++:
   xR.parent = yR;
 }
```

2.5. Monotone Queue. Used in sliding window algorithms where one would like to find the minimum in each interval of a given length. Amortized  $\mathcal{O}(n)$  to find min in each of these intervals in an array of length n. Can easily be used to find the maximum as well.

```
private static class MinMonQue {
   LinkedList<Integer> que = new LinkedList<>();
   public void add(int i) {
      while(!que.isEmpty() && que.getFirst() > i)
            que.removeFirst();
      que.addFirst(i);
   }
   public int last() {
      return que.getLast();
   }
   public void remove(int i) {
      if(que.getLast() == i) que.removeLast();
   }
}
```

2.6. **Treap.** Treap is a binary search tree that uses randomization to balance itself. It's easy to implement, and gives you access to the internal structures of a binary tree, which can be used to find the k'th element for example. Because of the randomness, the average height is about a factor 4 of a prefectly balanced tree.

```
class Treap{
 int sz;
 int v;
 double v;
 Treap L, R;
 static int sz(Treap t) {
   if(t == null) return 0;
   return t.sz;
 static void update(Treap t) {
   if(t == null) return;
   t.sz = sz(t.L) + sz(t.R) + 1;
 static Treap merge(Treap a, Treap b) {
   if (a == null) return b;
   if(b == null) return a;
   if (a.y < b.y) {
     a.R = merge(a.R, b);
      update(a):
      return a;
   } else {
      b.L = merge(a, b.L);
```

```
Treap[] p = new Treap[]{t, r};
                                                                                                                              3. Graph Algorithms
    update(b);
    return b;
                                                            update(p[0]);
                                                                                                             3.1. Djikstras algorithm. Finds the shortest distance be-
                                                            update(p[1]);

3.3. **Network Flow.** The Floyd Warshall algorithm for determining the maximum flow through a graph can be used for a lot of unexpected problems. Given a problem that can be formulated as a graph, where no ideas are found trying, it might help trying to apply network flow. The running time is  $\mathcal{O}(C \cdot m)$  where C is the maximum flow and m is the amount of edges in the graph. If C is very large we can change the running time to  $\mathcal{O}(\log Cm^2)$  by only studying edges with a large enough capacity in the beginning.

```
import java.util.*;
class Node {
```

```
LinkedList<Edge> edges = new LinkedList<>();
                                                        }

```

5.1. System of Equations. Solves the system of equations 5.2. Convex Hull. From a collection of points in the plane Ax = b by Gaussian elimination. This can for example be used to determine the expected value of each node in a markov chain. Runns in  $\mathcal{O}(N^3)$ .

```
//Computes A^{-1} * b
static double[] solve(double[][] A, double[] b) {
 int N = b.length;
 // Gaussian elimination with partial pivoting
  for (int i = 0; i < N; i++) {
    // find pivot row and swap
    int max = i;
    for (int j = i + 1; j < N; j++)
      if (Math.abs(A[i][i]) > Math.abs(A[max][i]))
        max = i;
    double[] tmp = A[i];
    A[i] = A[max];
    A[max] = tmp;
    double tmp2 = b[i]:
    b[i] = b[max];
    b[max] = tmp2;
    // A doesn't have full rank
    if (Math.abs(A[i][i])<0.00001) return null:</pre>
    // pivot within b
    for (int j = i + 1; j < N; j++)
      b[j] = b[i] * A[j][i] / A[i][i];
    // pivot within A
    for (int j = i + 1; j < N; j++) {
      double m = A[i][i] / A[i][i];
      for (int k = i+1; k < N; k++)
        A[j][k] -= A[i][k] * m;
```

```
A[j][i] = 0.0;
// back substitution
double[] x = new double[N];
for (int j = N - 1; j >= 0; j--) {
 double t = 0.0;
  for (int k = j + 1; k < N; k++)
   t += A[i][k] * x[k]:
 x[i] = (b[i] - t) / A[i][i];
return x;
```

the convex hull is often used to compute the largest distance or the area covered, or the length of a rope that encloses the points. It can be found in  $\mathcal{O}(N \log N)$  time by sorting the points on angle and the sweeping over all of them.

### 6. NP Tricks

6.1. **MaxClique.** The max clique problem is one of Karp's 21 NP-complete problems. The problem is to find the lagest subset of an undirected graph that forms a clique - a complete graph. There is an obvious algorithm that just inspects every subset of the graph and determines if this subset is a clique. This algorithm runns in  $\mathcal{O}(n^2 2^n)$ . However one can use the meet in the middle trick (one step divide and conquier) and reduce the complexity to  $\mathcal{O}(n^2 2^{\frac{n}{2}})$ .

```
static int max_clique(int n, int[][] adj) {
 int fst = n/2;
 int snd = n - fst:
  int[] maxc = new int[1<<fst];</pre>
  int max = 1;
  for(int i = 0; i < (1 << fst); i++) {
    for(int a = 0; a<fst; a++) {</pre>
      if((i&1<<a) != 0)
        maxc[i] = Math.max(maxc[i], maxc[i^(1<<a)]);
   boolean ok = true;
    for(int a = 0; a<fst; a++) if((i&1<<a) != 0) {
      for(int b = a+1: b<fst: b++) {
          if((i\&1 << b) != 0 \&\& adj[a][b] == 0)
              ok = false;
     }
   if(ok) {
      maxc[i] = Integer.bitCount(i);
      max = Math.max(max, maxc[i]);
  for(int i = 0; i < (1 << snd); i++) {
   boolean ok = true;
   for(int a = 0; a<snd; a++) if((i&1<<a) != 0) {
      for(int b = a+1; b<snd; b++) {</pre>
        if((i\&1 << b) != 0)
          if(adj[a+fst][b+fst] == 0)
            ok = false;
     }
   if(!ok) continue;
    int mask = 0:
    for(int a = 0; a<fst; a++) {</pre>
      ok = true;
      for(int b = 0; b < snd; b++) {
       if((i&1<<b) != 0) {
          if(adj[a][b+fst] == 0) ok = false;
       }
      if(ok) mask |= (1 << a);
    max = Math.max(Integer.bitCount(i) + maxc[mask],
            max);
```

```
}
return max;
```

## 7. Coordinate Geometry

7.1. **Area of a nonintersecting polygon.** The signed area of a polygon with n vertices is given by

$$A = \frac{1}{2} \sum_{i=0}^{n-1} (x_i y_{i+1} - x_{i+1} y_i)$$

7.2. **Intersection of two lines.** Two lines defined by

$$a_1x + b_1y + c_1 = 0$$
$$a_2x + b_2y + c_2 = 0$$

Intersects in the point

$$P = \left(\frac{b_1c_2 - b_2c_1}{w}, \frac{a_2c_1 - a_1c_2}{w}\right),$$

where  $w = a_1b_2 - a_2b_1$ . If w = 0 the lines are parallell.

7.3. Distance between line segment and point. Given a linesegment between point P, Q, the distance D to point R is given by:

$$\begin{split} &a = Q_y - P_y \\ &b = Q_x - P_x \\ &c = P_x Q_y - P_y Q_x \\ &R_P = (\frac{b(bR_x - aR_y) - ac}{a^2 + b^2}, \frac{a(aR_y - bR_x) - bc}{a^2 + b^2}) \\ &D = \begin{cases} \frac{|aR_x + bR_y + c|}{\sqrt{a^2 + b^2}} & \text{if } (R_{P_x} - P_x)(R_{P_x} - Q_x) < 0, \\ \min |P - R|, |Q - R| & \text{otherwise} \end{cases} \end{split}$$

- 7.4. **Picks theorem.** Find the amount of internal integer coordinates i inside a polygon with picks theorem  $A = \frac{b}{2} + i 1$ , where A is the area of the polygon and b is the amount of coordinates on the boundary.
- 7.5. Implementations.

import math

# Distance between two points

```
 \begin{array}{c} \text{def dist}(p,\ q): \\ \text{return math.hypot}(p[\theta]\text{-}q[\theta],\ p[1]\ \text{-}\ q[1]) \end{array}
```

```
# Converts two points to a line (a, b, c),

8. Acieving AC on a solved problem

### 8.1. **WA**.

- Check that minimal input passes.
- Can an int overflow?
- Reread the problem statement.
- Start creating small testcases with python.
- Does cout print with high enough precision?
- Abstract the implementation.

### 8.2. **TLE.**

- Is the solution sanity checked?
- Use pypy instead of python.
- Rewrite in C++ or Java.
- Can we apply DP anywhere?
- To minimize penalty time you should create a worst case input (if easy) to test on.

## 8.3. **RTE**.

- Recursion limit in python?
- Arrayindex out of bounds?
- Division by 0?
- Modifying iterator while iterating over it?
- Not using a well definied operator for Collections.sort?
- If nothing makes sense and the end of the contest is approaching you can binary search over where the error is with try-except.

#### 8.4. MLE.

- Create objects outside recursive function.
- Rewrite recursive solution to itterative with an own stack.

# 9. Practice Contest Checklist

- Operations per second in py2
- Operations per second in py3
- Operations per second in java
- Operations per second in c++
- Operations per second on local machine
- Is MLE called MLE or RTE?
- What happens if extra output is added? What about one extra new line or space?
- Look at documentation on judge.
- Submit a clar.
- Print.
- Directory with test cases.
