                                                                                if(root.li>=l && root.ri<=r)</pre>
    }
                                                                                  return root.sum; //max/min
                                                                                if(root.ri<l || root.li > r)
  public long sum(int i) {
                                                                                  return 0: //minInt/maxInt
    long sum = 0;
                                                                                else //max/min
    while(i>0) {
                                                                                  return getSum(root.lN,l,r) + getSum(root.rN,l,r);
      sum += data[i];
      i -= i&-i;
                                                                              static int update(ST root, int i, int val) {
                                                                                int diff = 0;
    return sum;
                                                                                if(root.li==root.ri && i == root.li) {
                                                                                  diff = val-root.sum; //max/min
                                                                                  root.sum=val; //max/min
2.2. Segment Tree. More general than a fenwick tree. Can adapt other operations
                                                                                  return diff; //root.max
than sum, e.g. min and max.
                                                                                int mid = (root.li + root.ri) / 2;
private static class ST {
                                                                                if (i <= mid) diff = update(root.lN, i, val);</pre>
  int li, ri;
                                                                                else diff = update(root.rN, i, val);
  int sum; //change to max/min
                                                                                root.sum+=diff; //ask other child
  ST lN:
                                                                                return diff; //and compute max/min
  ST rN;
static ST makeSqmTree(int[] A, int l, int r) {
  if(l == r) {
    ST node = new ST();
```

4

2.3. Lazy Segment Tree. More general implementation of a segment tree where its possible to increase whole segments by some diff, with lazy propagation. Implemented with arrays instead of nodes, which probably has less overhead to write during a competition.

```
class LazySegmentTree {
  private int n;
 private int[] lo, hi, sum, delta;
  public LazySegmentTree(int n) {
   this.n = n;
   lo = new int[4*n + 1];
   hi = new int[4*n + 1];
   sum = new int[4*n + 1];
   delta = new int[4*n + 1];
   init();
  public int sum(int a, int b) {
   return sum(1, a, b);
  private int sum(int i, int a, int b) {
   if(b < lo[i] || a > hi[i]) return 0;
   if(a <= lo[i] && hi[i] <= b) return sum(i);
   prop(i);
   int l = sum(2*i, a, b);
   int r = sum(2*i+1, a, b);
   update(i);
   return l + r;
  public void inc(int a, int b, int v) {
   inc(1, a, b, v);
  private void inc(int i, int a, int b, int v) {
   if(b < lo[i] || a > hi[i]) return;
   if(a <= lo[i] && hi[i] <= b) {
     delta[i] += v;
     return;
   }
   prop(i);
   inc(2*i, a, b, v);
   inc(2*i+1, a, b, v);
```

```
update(i);
private void init() {
 init(1, 0, n-1, new int[n]);
private void init(int i, int a, int b, int[] v) {
 lo[i] = a:
 hi[i] = b;
 if(a == b) {
   sum[i] = v[a];
   return;
 int m = (a+b)/2;
 init(2*i, a, m, v);
 init(2*i+1, m+1, b, v);
 update(i);
private void update(int i) {
  sum[i] = sum(2*i) + sum(2*i+1);
private int range(int i) {
 return hi[i] - lo[i] + 1;
private int sum(int i) {
  return sum[i] + range(i)*delta[i];
private void prop(int i) {
 delta[2*i] += delta[i]:
 delta[2*i+1] += delta[i];
  delta[i] = 0;
```

2.4. **Union Find.** This data structure is used in varoius algorithms, for example Kruskals algorithm for finding a Minimal Spanning Tree in a weighted graph. Also it can be used for backward simulation of dividing a set.

```
private class Node {
  Node parent;
  int h;
```

```
public Node() {
    parent = this;
    h = 0;
}
public Node find() {
    if(parent != this) parent = parent.find();
    return parent;
}
}
static void union(Node x, Node y) {
    Node xR = x.find(), yR = y.find();
    if(xR == yR) return;
    if(xR.h > yR.h)
        yR.parent = xR;
else {
    if(yR.h == xR.h) yR.h++;
        xR.parent = yR;
}
```

2.5. Monotone Queue. Used in sliding window algorithms where one would like to find the minimum in each interval of a given length. Amortized $\mathcal{O}(n)$ to find min in each of these intervals in an array of length n. Can easily be used to find the maximum as well.

```
private static class MinMonQue {
    LinkedList<Integer> que = new LinkedList<>();
    public void add(int i) {
        while(!que.isEmpty() && que.getFirst() > i)
            que.removeFirst();
        que.addFirst(i);
    }
    public int last() {
        return que.getLast();
    }
    public void remove(int i) {
        if(que.getLast() == i) que.removeLast();
    }
}
```

2.6. **Treap.** Treap is a binary search tree that uses randomization to balance itself. It's easy to implement, and gives you access to the internal structures of a binary tree,

which can be used to find the k'th element for example. Because of the randomness, the average height is about a factor 4 of a prefectly balanced tree.

```
class Treap{
 int sz:
 int v;
 double y;
 Treap L, R;
 static int sz(Treap t) {
   if(t == null) return 0;
   return t.sz;
 static void update(Treap t) {
   if(t == null) return:
   t.sz = sz(t.L) + sz(t.R) + 1;
 static Treap merge(Treap a, Treap b) {
   if (a == null) return b;
   if(b == null) return a;
   if (a.y < b.y) {
     a.R = merge(a.R, b);
     update(a);
      return a;
   } else {
     b.L = merge(a, b.L);
     update(b);
      return b;
 //inserts middle in left half
 static Treap[] split(Treap t, int x) {
   if (t == null) return new Treap[2];
   if (t.v <= x) {
     Treap[] p = split(t.R, x);
     t.R = p[0];
     p[0] = t;
     return p;
   } else {
     Treap[] p = split(t.L, x);
     t.L = p[1];
```

```
p[1] = t;
    return p;
//use only with split
static Treap insert(Treap t, int x) {
 Treap m = new Treap();
  m \cdot v = x:
  m.y = Math.random();
  m.sz = 1;
  Treap[] p = splitK(t, x-1);
  return merge(merge(p[0],m), p[1]);
//inserts middle in left half
static Treap[] splitK(Treap t, int x) {
  if (t == null) return new Treap[2];
  if (t.sz < x) return new Treap[]{t, null};</pre>
  if (sz(t.L) >= x) {
    Treap[] p = splitK(t.L, x);
    t.L = p[1];
    p[1] = t;
    update(p[0]);
    update(p[1]);
    return p;
  } else if (sz(t.L) + 1 == x){
    Treap r = t.R;
    t.R = null:
    Treap[] p = new Treap[]{t, r};
    update(p[0]);
    update(p[1]);
    return p;
  } else {
    Treap[] p = splitK(t.R, x - sz(t.L)-1);
    t.R = p[0];
    p[0] = t;
    update(p[0]);
    update(p[1]);
    return p;
```

```
//use only with splitK
static Treap insertK(Treap t, int w, int x) {
 Treap m = new Treap();
 m.v = x;
 m.y = Math.random();
 m.sz = 1:
 Treap[] p = splitK(t, w);
 t = merge(p[0], m);
  return merge(t, p[1]);
//use only with splitK
static Treap deleteK(Treap t, int w, int x) {
 Treap[] p = splitK(t, w);
 Treap[] q = splitK(p[0], w-1);
  return merge(q[0], p[1]);
static Treap Left(Treap t) {
 if (t == null) return null:
 if (t.L == null) return t;
  return Left(t.L);
static Treap Right(Treap t) {
 if (t == null) return null;
 if (t.R == null) return t;
  return Right(t.R);
```

3. Graph Algorithms

3.1. **Djikstras algorithm.** Finds the shortest distance between two Nodes in a weighted graph in $\mathcal{O}(|E|\log|V|)$ time.

```
//Requires java.util.LinkedList and java.util.TreeSet
private static class Node implements Comparable<Node>{
  LinkedList<Edge> edges = new LinkedList<>();
  int w;
```

7

```
int id;
  public Node(int id) {
   w = Integer.MAX_VALUE;
   this.id = id;
  public int compareTo(Node n) {
   if(w != n.w) return w - n.w;
   return id - n.id:
 //Asumes all nodes have weight MAXINT.
  public int djikstra(Node x) {
   this.w = 0;
   TreeSet<Node> set = new TreeSet<>();
   set.add(this);
   while(!set.isEmpty()) {
     Node curr = set.pollFirst();
     if(x == curr) return x.w;
     for(Edge e: curr.edges) {
        Node other = e.u == curr? e.v : e.u;
        if(other.w > e.cost + curr.w) {
          set.remove(other):
          other.w = e.cost + curr.w;
          set.add(other):
   return -1;
private static class Edge {
 Node u,v;
 int cost;
  public Edge(Node u, Node v, int c) {
   this.u = u; this.v = v;
   cost = c;
```

3.2. **Bipartite Graphs.** The Hopcroft-Karp algorithm finds the maximal matching in a bipartite graph. Also, this matching can together with Könings theorem be used

to construct a minimal vertex-cover, which as we all know is the complement of a maximum independent set. Runs in $\mathcal{O}(|E|\sqrt{|V|})$. import java.util.*; class Node { int id; LinkedList<Node> ch = new LinkedList<>(); public Node(int id) { this.id = id; public class BiGraph { private static int INF = Integer.MAX_VALUE; LinkedList<Node> L, R; int N. 3.3. **Network Flow.** The Floyd Warshall algorithm for determining the maximum flow through a graph can be used for a lot of unexpected problems. Given a problem that can be formulated as a graph, where no ideas are found trying, it might help trying to apply network flow. The running time is $\mathcal{O}(C \cdot m)$ where C is the maximum flow and m is the amount of edges in the graph. If C is very large we can change the

```
running time to \mathcal{O}(\log Cm^2) by only studying edges with a large enough capacity in
                                                                               Edge redge = new Edge(Nv, Nu, 0, edgec++);
the beginning.
                                                                               edge.redge = redge;
                                                                               redge.redge = edge;
import java.util.*;
                                                                               real.add(edge);

return out;
}
```

3.4. **Min Cost Max Flow.** Finds the minimal cost of a maximum flow through a graph. Can be used for some optimization problems where the optimal assignment needs to be a maximum flow.

```
class MinCostMaxFlow {
boolean found[];
int N, dad[];
long cap[][], flow[][], cost[][], dist[], pi[];
static final long INF = Long.MAX_VALUE / 2 - 1;
boolean search(int s, int t) {
Arrays.fill(found, false);
Arrays.fill(dist, INF);
dist[s] = 0;
while (s != N) {
  int best = N;
  found[s] = true;
  for (int k = 0; k < N; k++) {
   if (found[k]) continue;
   if (flow[k][s] != 0) {
      long val = dist[s] + pi[s] - pi[k] - cost[k][s];
     if (dist[k] > val) {
       dist[k] = val;
       dad[k] = s;
    if (flow[s][k] < cap[s][k]) {
```

```
long val = dist[s] + pi[s] - pi[k] + cost[s][k];
      if (dist[k] > val) {
        dist[k] = val;
        dad[k] = s;
    }
    if (dist[k] < dist[best]) best = k;</pre>
  s = best;
for (int k = 0; k < N; k++)
  pi[k] = Math.min(pi[k] + dist[k], INF);
return found[t];
long[] mcmf(long c[][], long d[][], int s, int t) {
cap = c;
cost = d;
N = cap.length;
found = new boolean[N];
flow = new long[N][N];
dist = new long[N+1];
dad = new int[N];
pi = new long[N];
long totflow = 0, totcost = 0;
while (search(s, t)) {
  long amt = INF;
  for (int x = t; x != s; x = dad[x])
    amt = Math.min(amt, flow[x][dad[x]] != 0 ?
    flow[x][dad[x]] : cap[dad[x]][x] - flow[dad[x]][x]);
  for (int x = t; x != s; x = dad[x]) {
    if (flow[x][dad[x]] != 0) {
      flow[x][dad[x]] -= amt;
      totcost -= amt * cost[x][dad[x]];
    } else {
      flow[dad[x]][x] += amt;
      totcost += amt * cost[dad[x]][x];
```

```
}
}
totflow += amt;
}
return new long[]{ totflow, totcost };
}
}
```

4. Dynamic Programming

4.1. Longest Increasing Subsequence. Finds the longest increasing subsequence in an array in $\mathcal{O}(n \log n)$ time. Can easility be transformed to longest decreasing/nondecreasing/nonincreasing subsequence.

```
public static int lis(int[] X) {
 int n = X.length;
  int P[] = new int[n];
 int M[] = new int[n+1];
  int L = 0;
  for(int i = 0; i < n; i++) {
   int lo = 1;
   int hi = L;
   while(lo<=hi) {</pre>
      int mid = lo + (hi - lo + 1)/2;
      if(X[M[mid]]<X[i])</pre>
        lo = mid+1;
      else
        hi = mid-1;
    int newL = lo;
   P[i] = M[newL-1];
   M[newL] = i;
   if (newL > L)
     L = newL;
  int[] S = new int[L];
  int k = M[L];
 for (int i = L-1; i > = 0; i - -) {
   S[i] = k; //or X[k]
```

```
k = P[k];
}
return L; // or S
}
```

4.2. **String functions.** The z-function computes the longest common prefix of t and t[i:] for each i in $\mathcal{O}(|t|)$. The border function computes the longest common proper (smaller than whole string) prefix and suffix of string t[:i].

```
def zfun(t):
    z = [0]*len(t)
    n = len(t)
    l, r = (0,0)
    for i in range(1,n):
        if i < r:
            z[i] = min(z[i-l], r-i+1)
        while z[i] + i < n and t[i+z[i]] == t[z[i]]:
            z[i]+=1
        if i + z[i] - 1 > r:
            l = i
            r = i + z[i] - 1
    return z
def matches(t, p):
    s = p + '#' + t
    return filter(lambda x: x[1] == len(p),
            enumerate(zfun(s)))
def boarders(s):
    b = [0]*len(s)
    for i in range(1, len(s)):
        k = b[i-1]
        while k>0 and s[k] != s[i]:
            k = b[k-1]
        if s[k] == s[i]:
            b[i] = k+1
    return b
```

5. Etc

5.1. System of Equations. Solves the system of equations Ax = b by Gaussian elimination. This can for example be used to determine the expected value of each node in a markov chain. Runns in $\mathcal{O}(N^3)$.

```
//Computes A^{-1} * b
static double[] solve(double[][] A, double[] b) {
  int N = b.length;
 // Gaussian elimination with partial pivoting
  for (int i = 0; i < N; i++) {
   // find pivot row and swap
   int max = i:
    for (int j = i + 1; j < N; j++)
     if (Math.abs(A[j][i]) > Math.abs(A[max][i]))
        max = j;
    double[] tmp = A[i];
   A[i] = A[max];
   A[max] = tmp;
    double tmp2 = b[i];
   b[i] = b[max];
   b[max] = tmp2;
   // A doesn't have full rank
   if (Math.abs(A[i][i])<0.00001) return null;</pre>
   // pivot within b
   for (int j = i + 1; j < N; j++)
      b[i] = b[i] * A[i][i] / A[i][i];
   // pivot within A
    for (int j = i + 1; j < N; j++) {
      double m = A[j][i] / A[i][i];
      for (int k = i+1; k < N; k++)
       A[j][k] -= A[i][k] * m;
      A[i][i] = 0.0;
   }
  // back substitution
  double[] x = new double[N];
  for (int j = N - 1; j >= 0; j --) {
    double t = 0.0:
   for (int k = j + 1; k < N; k++)
     t += A[j][k] * x[k];
```

```
x[j] = (b[j] - t) / A[j][j];
}
return x;
}
```

5.2. Convex Hull. From a collection of points in the plane the convex hull is often used to compute the largest distance or the area covered, or the length of a rope that encloses the points. It can be found in $\mathcal{O}(N \log N)$ time by sorting the points on angle and the sweeping over all of them.

```
import java.util.*;
public class ConvexHull {
  static class Point implements Comparable<Point> {
    static Point xmin;
    int x, y;
    public Point(int x, int y) {
      this.x = x; this.y = y;
    public int compareTo(Point p) {
      int c = cross(this, xmin, p);
     if(c!=0) return c;
      double d = dist(this,xmin) - dist(p,xmin);
      return (int) Math.signum(d);
  static double dist(Point p1, Point p2) {
    return Math.hypot(p1.x - p2.x, p1.y - p2.y);
  static int cross(Point a, Point b, Point c) {
    int dx1 = b.x - a.x;
    int dy1 = b.y - a.y;
    int dx2 = c.x - b.x;
    int dv2 = c.v - b.v;
    return dx1*dy2 - dx2*dy1;
  Point[] convexHull(Point[] S) {
    int N = S.length;
    // find a point on the convex hull.
    Point xmin = S[0];
    int id = 0;
    for(int i = 0; i < N; i++) {
```

```
Point p = S[i];
  if(xmin.x > p.x | |
     xmin.x == p.x \&\& xmin.y > p.y) {
    xmin = p;
    id = i;
S[id] = S[N-1]:
S[N-1] = xmin;
Point.xmin = xmin;
// Sort on angle to xmin.
Arrays.sort(S, 0, N-1);

6. NP Tricks

6.1. **MaxClique.** The max clique problem is one of Karp's 21 NP-complete problems. The problem is to find the lagest subset of an undirected graph that forms a clique - a complete graph. There is an obvious algorithm that just inspects every subset of the graph and determines if this subset is a clique. This algorithm runns in $\mathcal{O}(n^2 2^n)$. However one can use the meet in the middle trick (one step divide and conqurer) and reduce the complexity to $\mathcal{O}(n^2 2^{\frac{n}{2}})$.

```
static int max_clique(int n, int[][] adj) {
 int fst = n/2;
 int snd = n - fst;
 int[] maxc = new int[1<<fst];</pre>
  int max = 1;
  for(int i = 0; i < (1 << fst); i++) {
   for(int a = 0; a<fst; a++) {
     if((i&1<<a) != 0)
        maxc[i] = Math.max(maxc[i], maxc[i^(1<<a)]);
   boolean ok = true;
   for(int a = 0; a<fst; a++) if((i\&1 << a) != 0) {
     for(int b = a+1; b<fst; b++) {
          if((i&1<<b) != 0 && adj[a][b] == 0)
              ok = false:
      }
   if(ok) {
     maxc[i] = Integer.bitCount(i);
     max = Math.max(max, maxc[i]);
```

```
for(int i = 0; i < (1 << snd); i++) {
  boolean ok = true;
 for(int a = 0; a<snd; a++) if((i&1<<a) != 0) {
    for(int b = a+1; b < snd; b++) {
     if((i&1<<b) != 0)
        if(adj[a+fst][b+fst] == 0)
          ok = false;
    }
 if(!ok) continue;
 int mask = 0:
  for(int a = 0; a<fst; a++) {
    ok = true:
    for(int b = 0; b < snd; b++) {
     if((i&1<<b) != 0) {
        if(adj[a][b+fst] == 0) ok = false;
    if(ok) mask = (1 << a):
 max = Math.max(Integer.bitCount(i) + maxc[mask],
          max);
return max;
```

7. Coordinate Geometry

7.1. Area of a nonintersecting polygon. The signed area of a polygon with n verticies is given by

$$A = \frac{1}{2} \sum_{i=0}^{n-1} (x_i y_{i+1} - x_{i+1} y_i)$$

7.2. Intersection of two lines. Two lines defined by

$$a_1x + b_1y + c_1 = 0$$
$$a_2x + b_2y + c_2 = 0$$

Intersects in the point

$$P = (\frac{b_1c_2 - b_2c_1}{w}, \frac{a_2c_1 - a_1c_2}{w}),$$

where $w = a_1b_2 - a_2b_1$. If w = 0 the lines are parallell.

7.3. Distance between line segment and point. Given a linesegment between point P, Q, the distance D to point R is given by:

$$\begin{split} a &= Q_y - P_y \\ b &= Q_x - P_x \\ c &= P_x Q_y - P_y Q_x \\ R_P &= (\frac{b(bR_x - aR_y) - ac}{a^2 + b^2}, \frac{a(aR_y - bR_x) - bc}{a^2 + b^2}) \\ D &= \begin{cases} \frac{|aR_x + bR_y + c|}{\sqrt{a^2 + b^2}} & \text{if } (R_{P_x} - P_x)(R_{P_x} - Q_x) < 0, \\ \min |P - R|, |Q - R| & \text{otherwise} \end{cases} \end{split}$$

7.4. **Picks theorem.** Find the amount of internal integer coordinates i inside a polygon with picks theorem $A = \frac{b}{2} + i - 1$, where A is the area of the polygon and b is the amount of coordinates on the boundary.

7.5. Implementations.

8. Acieving AC on a solved problem

18

8.1. **WA**.

- Check that minimal input passes.
- Can an int overflow?
- Reread the problem statement.
- Start creating small testcases with python.
- Does cout print with high enough precision?
- Abstract the implementation.

8.2. **TLE.**

- Is the solution sanity checked?
- Use pypy instead of python.
- Rewrite in C++ or Java.
- Can we apply DP anywhere?
- To minimize penalty time you should create a worst case input (if easy) to test on
- Binary Search over the answer?

8.3. **RTE.**

- Recursion limit in python?
- Arrayindex out of bounds?
- Division by 0?
- Modifying iterator while iterating over it?
- Not using a well definied operator for Collections.sort?
- If nothing makes sense and the end of the contest is approaching you can binary search over where the error is with try-except.

8.4. **MLE**.

- Create objects outside recursive function.
- Rewrite recursive solution to itterative with an own stack.

9. Practice Contest Checklist

- Operations per second in py2
- Operations per second in py3
- Operations per second in java
- Operations per second in c++
- Operations per second on local machine
- Is MLE called MLE or RTE?
- What happens if extra output is added? What about one extra new line or space?
- Look at documentation on judge.
- Submit a clar.
- Print a file.
- Directory with test cases.
