} catch (IOException e) { }
return token;
}
private String nextToken() {
String ans = peekToken();
token = null;
return ans;
}
}
```

2. Data Structures

2.1. Binary Indexed Tree. Also called a fenwick tree. Builds in $\mathcal{O}(n \log n)$ from an array. Querry sum from 0 to i in $\mathcal{O}(\log n)$ and updates an element in $\mathcal{O}(\log n)$.

```
private static class BIT {
  long[] data;
  public BIT(int size) {
    data = new long[size+1];
  }
  public void update(int i, int delta) {
    while(i < data.length) {
      data[i] += delta;
      i += i&-i; // Integer.lowestOneBit(i);
    }
  }
  public long sum(int i) {
    long sum = 0;
    while(i>0) {
      sum += data[i];
      i -= i&-i;
    }
    return sum;
  }
}
```

2.2. **Segment Tree.** More general than a fenwick tree. Can adapt other operations than sum, e.g. min and max.

```
private static class ST {
  int li, ri;
  int sum; //change to max/min
  ST lN;
```

```
ST rN;
static ST makeSgmTree(int[] A, int l, int r) {
 if(l == r) {
   ST node = new ST();
   node.li = l;
    node.ri = r;
    node.sum = A[l]; //max/min
    return node:
  int mid = (l+r)/2;
  ST lN = makeSgmTree(A,l,mid);
  ST rN = makeSgmTree(A,mid+1,r);
  ST root = new ST();
  root.li = lN.li;
  root.ri = rN.ri:
  root.sum = lN.sum + rN.sum: //max/min
  root.lN = lN:
  root.rN = rN;
  return root:
static int getSum(ST root, int l, int r) {//max/min
 if(root.li>=l && root.ri<=r)</pre>
    return root.sum; //max/min
 if(root.ri<l || root.li > r)
    return 0; //minInt/maxInt
  else //max/min
    return getSum(root.lN,l,r) + getSum(root.rN,l,r);
static int update(ST root, int i, int val) {
 int diff = 0:
 if(root.li==root.ri && i == root.li) {
    diff = val-root.sum: //max/min
    root.sum=val; //max/min
    return diff; //root.max
 int mid = (root.li + root.ri) / 2;
 if (i <= mid) diff = update(root.lN, i, val);</pre>
  else diff = update(root.rN, i, val);
  root.sum+=diff; //ask other child
  return diff; //and compute max/min
```

2.3. Lazy Segment Tree. More general implementation of a segment tree where its possible to increase whole segments by some diff, with lazy propagation. Implemented with arrays instead of nodes, which probably has less overhead to write during a competition.

```
class LazySegmentTree {
 private int n:
 private int[] lo, hi, sum, delta;
 public LazySegmentTree(int n) {
   this.n = n;
   lo = new int[4*n + 1]:
   hi = new int[4*n + 1];
   sum = new int[4*n + 1];
   delta = new int[4*n + 1];
   init():
 public int sum(int a, int b) {
   return sum(1, a, b);
 private int sum(int i, int a, int b) {
   if(b < lo[i] || a > hi[i]) return 0:
   if(a \leftarrow lo[i] && hi[i] \leftarrow b) return sum(i);
   prop(i);
   int l = sum(2*i, a, b);
   int r = sum(2*i+1, a, b);
   update(i);
   return l + r;
 public void inc(int a, int b, int v) {
   inc(1. a. b. v):
 private void inc(int i, int a, int b, int v) {
   if(b < lo[i] || a > hi[i]) return;
   if(a <= lo[i] && hi[i] <= b) {
     delta[i] += v;
      return;
   prop(i):
   inc(2*i, a, b, v);
   inc(2*i+1, a, b, v);
   update(i);
```

```
private void init() {
  init(1, 0, n-1, new int[n]);
private void init(int i, int a, int b, int[] v) {
  lo[i] = a;
  hi[i] = b;
  if(a == b) {
    sum[i] = v[a]:
    return;
  int m = (a+b)/2;
  init(2*i. a. m. v):
  init(2*i+1, m+1, b, v);
  update(i);
private void update(int i) {
  sum[i] = sum(2*i) + sum(2*i+1);
private int range(int i) {
  return hi[i] - lo[i] + 1;
private int sum(int i) {
  return sum[i] + range(i)*delta[i];
private void prop(int i) {
  delta[2*i] += delta[i];
  delta[2*i+1] += delta[i];
  delta[i] = 0;
```

2.4. **Union Find.** This data structure is used in varoius algorithms, for example Kruskals algorithm for finding a Minimal Spanning Tree in a weighted graph. Also it can be used for backward simulation of dividing a set.

```
private class Node {
  Node parent;
  int h;
  public Node() {
    parent = this;
    h = 0;
  }
  public Node find() {
```

```
if(parent != this) parent = parent.find();
  return parent;
}

static void union(Node x, Node y) {
  Node xR = x.find(), yR = y.find();
  if(xR == yR) return;
  if(xR.h > yR.h)
    yR.parent = xR;
  else {
    if(yR.h == xR.h) yR.h++;
    xR.parent = yR;
}
```

2.5. Monotone Queue. Used in sliding window algorithms where one would like to find the minimum in each interval of a given length. Amortized $\mathcal{O}(n)$ to find min in each of these intervals in an array of length n. Can easily be used to find the maximum as well.

```
private static class MinMonQue {
   LinkedList<Integer> que = new LinkedList<>();
   public void add(int i) {
      while(!que.isEmpty() && que.getFirst() > i)
            que.removeFirst();
      que.addFirst(i);
   }
   public int last() {
      return que.getLast();
   }
   public void remove(int i) {
      if(que.getLast() == i) que.removeLast();
   }
}
```

2.6. **Treap.** Treap is a binary search tree that uses randomization to balance itself. It's easy to implement, and gives you access to the internal structures of a binary tree, which can be used to find the k'th element for example. Because of the randomness, the average height is about a factor 4 of a prefectly balanced tree.

```
class Treap{
  int sz;
  int v;
```

```
double y;
Treap L, R;
static int sz(Treap t) {
 if(t == null) return 0;
  return t.sz;
static void update(Treap t) {
 if(t == null) return:
  t.sz = sz(t.L) + sz(t.R) + 1;
static Treap merge(Treap a, Treap b) {
 if (a == null) return b:
  if(b == null) return a;
  if (a.v < b.v) {
    a.R = merge(a.R, b);
    update(a);
    return a;
  } else {
    b.L = merge(a, b.L);
    update(b);
    return b;
//inserts middle in left half
static Treap[] split(Treap t, int x) {
  if (t == null) return new Treap[2];
  if (t.v <= x) {
    Treap[] p = split(t.R, x);
    t.R = p[0];
    p[0] = t;
    return p;
  } else {
    Treap[] p = split(t.L, x);
    t.L = p[1];
    p[1] = t;
    return p;
//use only with split
static Treap insert(Treap t, int x) {
 Treap m = new Treap();
  m.v = x;
  m.y = Math.random();
```

}

```
m.sz = 1;
  Treap[] p = splitK(t, x-1);
  return merge(merge(p[0],m), p[1]);
//inserts middle in left half
static Treap[] splitK(Treap t, int x) {
  if (t == null) return new Treap[2]:
  if (t.sz < x) return new Treap[]{t, null};</pre>
  if (sz(t.L) >= x) {
    Treap[] p = splitK(t.L, x);
    t.L = p[1];
    p[1] = t;
    update(p[0]);
    update(p[1]);
    return p;
  } else if (sz(t.L) + 1 == x){
    Treap r = t.R;
    t.R = null;
    Treap[] p = new Treap[]{t, r};
    update(p[0]);
    update(p[1]);
    return p;
  } else {
    Treap[] p = splitK(t.R, x - sz(t.L)-1);
    t.R = p[0];
    p[0] = t;
    update(p[0]);
    update(p[1]);
    return p;
  }
//use only with splitK
static Treap insertK(Treap t, int w, int x) {
  Treap m = new Treap();
  m.v = x:
  m.y = Math.random();
  m.sz = 1;
  Treap[] p = splitK(t, w);
  t = merge(p[0], m);
  return merge(t, p[1]);
//use only with splitK
```

```
for(Edge e: curr.edges) {
static Treap deleteK(Treap t, int w, int x) {
 Treap[] p = splitK(t, w);
                                                             Node other = e.u == curr? e.v : e.u;
 Treap[] q = splitK(p[0], w-1);
                                                             if(other.w > e.cost + curr.w) {
                                                               set.remove(other);
 return merge(q[0], p[1]);
                                                               other.w = e.cost + curr.w;
                                                               set.add(other);
static Treap Left(Treap t) {
 if (t == null) return null;
                                                          }
 if (t.L == null) return t:
 return Left(t.L);
                                                         return -1;
static Treap Right(Treap t) {
 if (t == null) return null:
                                                     private static class Edge {
 if (t.R == null) return t;
                                                      Node u,v;
 return Right(t.R);
                                                       int cost;
                                                       public Edge(Node u, Node v, int c) {
                                                        this.u = u; this.v = v;
                                                         cost = c;
                                                    }
             3. Graph Algorithms
```

3.1. **Dikstras algorithm.** Finds the shortest distance between two Nodes in a weighted graph in $\mathcal{O}(|E|\log|V|)$ time.

```
//Requires java.util.LinkedList and java.util.TreeSet
  LinkedList<Edge> edges = new LinkedList<>():
 int w;
  int id;
  public Node(int id) {
   w = Integer.MAX_VALUE;
    this.id = id;
  public int compareTo(Node n) {
   if(w != n.w) return w - n.w;
    return id - n.id;
 //Asumes all nodes have weight MAXINT.
  public int djikstra(Node x) {
    this.w = 0:
   TreeSet<Node> set = new TreeSet<>():
    set.add(this):
   while(!set.isEmpty()) {
     Node curr = set.pollFirst();
     if(x == curr) return x.w;
```

3.2. Bipartite Graphs. The Hopcroft-Karp algorithm finds the maximal matching in a bipartite graph. Also, this matching can together with Könings theorem be used to construct a private static class Node implements Comparable<Node>{ minimal vertex-cover, which as we all know is the complement of a maximum independent set. Runs in $\mathcal{O}(|E|\sqrt{|V|})$.

```
import java.util.*;
class Node {
 int id:
 LinkedList<Node> ch = new LinkedList<>();
  public Node(int id) {
    this.id = id:
public class BiGraph {
  private static int INF = Integer.MAX_VALUE:
 LinkedList<Node> L, R;
  int N, M;
 Node[] U:
  int[] Pair, Dist;
  int nild:
  public BiGraph(LinkedList<Node> L, LinkedList<Node> R){
   N = L.size(); M = R.size();
    this.L = L; this.R = R;
```

```
U = new Node[N+M];
                                                           Pair = new int[M+N];
                                                                                                                    HashSet<Integer> K = new HashSet<>();
  for(Node n: L) U[n.id] = n;
                                                          Dist = new int[M+N];
                                                                                                                    for(Node n: L) if(!Z[n.id]) K.add(n.id);
                                                                                                                    for(Node n: R) if(Z[n.id]) K.add(n.id);
  for(Node n: R) U[n.id] = n;
                                                           for(int i = 0; i < M+N; i++) {
                                                                                                                    return K;
                                                             Pair[i] = -1;
private boolean bfs() {
                                                            Dist[i] = INF;
                                                                                                                 }
  LinkedList<Node> Q = new LinkedList<>();
  for(Node n: L)
                                                           HashMap<Integer, Integer> out = new HashMap<>();
                                                                                                               3.3. Network Flow. The Floyd Warshall algorithm for de-
   if(Pair[n.id] == -1) {
                                                          while(bfs()) {
                                                                                                               termining the maximum flow through a graph can be used
     Dist[n.id] = 0:
                                                             for(Node n: L) if(Pair[n.id] == -1)
                                                                                                               for a lot of unexpected problems. Given a problem that can
      Q.add(n);
                                                               dfs(n);
                                                                                                               be formulated as a graph, where no ideas are found trying, it
   }else
                                                                                                               might help trying to apply network flow. The running time is
      Dist[n.id] = INF;
                                                           for(Node n: L) if(Pair[n.id] != -1)
                                                                                                                \mathcal{O}(C \cdot m) where C is the maximum flow and m is the amount
                                                             out.put(n.id, Pair[n.id]);
                                                                                                               of edges in the graph. If C is very large we can change the
  nild = INF;
                                                           return out;
                                                                                                               running time to \mathcal{O}(\log Cm^2) by only studying edges with a
  while(!Q.isEmpty()) {
                                                                                                               large enough capacity in the beginning.
                                                         public HashSet<Integer> minVTC() {
    Node u = Q.removeFirst();
    if(Dist[u.id] < nild)</pre>
                                                          HashMap<Integer, Integer> Lm = maxMatch();
                                                                                                               import java.util.*;

                                                                                                                  if (newL > L)
                                                          while(!bfs.isEmpty()) {
                                                                                                                    L = newL:
   }
                                                            Node i = bfs.removeFirst();
                                                            for(Edge e: i.edges) {
  if(t.visited) {
                                                              int c = e.cap - flow.get(e.id);
                                                                                                                int[] S = new int[L];
    LinkedList<Edge> res = new LinkedList<>();
                                                              if (c > 0 \&\& !A.contains(e.sink)) {
                                                                                                                int k = M[L];
```

```
for (int i = L-1; i >= 0; i--) {
  S[i] = k; //or X[k]
  k = P[k];
}
return L; // or S
```

4.2. Knuuth Morris Pratt substring. Finds if w is a subarray to s in linear time.

```
//assumes s.length>=w.length
public static boolean kmp(int [] w, int [] s) {
 int T[] = new int[w.length];
 T[0] = -1; T[1] = 0;
 int m = 0, i = 2;
  while(i<w.length) {</pre>
    if(w[i-1] == w[m]) {
      T[i] = ++m;
      i++;
    } else if (m>0) {
      m = T[m];
    } else {
      T[i] = 0;
      i++;
 }
 m = 0; i = 0;
 while(m+i<s.length){</pre>
    if(w[i] == s[m+i]) {
      if(i == w.length - 1)
        return true; //m
      i++;
    } else {
      if(T[i] > -1) {
        m = m + i - T[i];
        i = T[i];
      } else {
        i = 0:
        m = m+1;
      }}}
  return false;
```

4.3. String functions. The z-function computes the longest common prefix of t and t[i:] for each i in $\mathcal{O}(|t|)$. The boarder function computes the longest common proper (smaller than whole string) prefix and suffix of string t[:i].

```
def zfun(t):
    z = [0]*len(t)
   n = len(t)
   l. r = (0.0)
    for i in range(1,n):
        if i < r:
            z[i] = min(z[i-l], r-i+1)
        while z[i] + i < n and t[i+z[i]] == t[z[i]]:
            z[i]+=1
       if i + z[i] - 1 > r:
            1 = i
            r = i + z[i] - 1
    return z
def matches(t, p):
   s = p + '#' + t
    return filter(lambda x: x[1] == len(p),
            enumerate(zfun(s)))
def boarders(s):
   b = [0]*len(s)
   for i in range(1, len(s)):
        k = b[i-1]
        while k>0 and s[k] != s[i]:
            k = b[k-1]
       if s[k] == s[i]:
            b[i] = k+1
    return b
                       5. Etc
```

5.1. System of Equations. Solves the system of equations 5.2. Convex Hull. From a collection of points in the plane Ax = b by Gaussian elimination. This can for example be used to determine the expected value of each node in a markov chain. Runns in $\mathcal{O}(N^3)$.

```
//Computes A^{-1} * b
static double[] solve(double[][] A, double[] b) {
 int N = b.length;
 // Gaussian elimination with partial pivoting
  for (int i = 0: i < N: i++) {
```

```
// find pivot row and swap
  int max = i:
  for (int j = i + 1; j < N; j++)
    if (Math.abs(A[i][i]) > Math.abs(A[max][i]))
  double[] tmp = A[i];
  A[i] = A[max];
  A[max] = tmp;
  double tmp2 = b[i]:
  b[i] = b[max];
  b[max] = tmp2;
  // A doesn't have full rank
  if (Math.abs(A[i][i])<0.00001) return null:</pre>
  // pivot within b
  for (int j = i + 1; j < N; j++)
    b[i] = b[i] * A[i][i] / A[i][i];
  // pivot within A
  for (int j = i + 1; j < N; j++) {
    double m = A[i][i] / A[i][i];
    for (int k = i+1; k < N; k++)
      A[j][k] -= A[i][k] * m;
    A[j][i] = 0.0;
}
// back substitution
double[] x = new double[N];
for (int j = N - 1; j >= 0; j - -) {
  double t = 0.0;
  for (int k = j + 1; k < N; k++)
    t += A[j][k] * x[k];
  x[i] = (b[i] - t) / A[i][i];
}
return x;
```

the convex hull is often used to compute the largest distance or the area covered, or the length of a rope that encloses the points. It can be found in $\mathcal{O}(N \log N)$ time by sorting the points on angle and the sweeping over all of them.

```
import java.util.*;
public class ConvexHull {
 static class Point implements Comparable<Point> {
    static Point xmin:
```

```
int x, y;
  public Point(int x, int y) {
    this.x = x; this.y = y;
  public int compareTo(Point p) {
    int c = cross(this, xmin, p);
    if(c!=0) return c;
    double d = dist(this,xmin) - dist(p,xmin);
    return (int) Math.signum(d);
static double dist(Point p1, Point p2) {
  return Math.hypot(p1.x - p2.x, p1.y - p2.y);
static int cross(Point a, Point b, Point c) {
  int dx1 = b.x - a.x:
  int dy1 = b.y - a.y;
  int dx2 = c.x - b.x;
  int dy2 = c.y - b.y;
  return dx1*dy2 - dx2*dy1;
Point[] convexHull(Point[] S) {
  int N = S.lenath:
 // find a point on the convex hull.
  Point xmin = S[0];
  int id = 0;
  for(int i = 0; i < N; i++) {
    Point p = S[i];
    if(xmin.x > p.x | |
       xmin.x == p.x \&\& xmin.y > p.y) {
      xmin = p;
      id = i;
   }
  S[id] = S[N-1];
  S[N-1] = xmin;
  Point.xmin = xmin;
 // Sort on angle to xmin.
 Arrays.sort(S, 0, N-1);
  Point[] H = new Point[N+1];
 H[0] = S[N-2];
  H[1] = xmin;
  for(int i = 0; i < N-1; i++)
    H[i+2] = S[i];
```

```
int M = 1;
// swipe over the points
for(int i = 2; i <= N; i++) {
  while(cross(H[M-1], H[M], H[i]) <= 0) {
   if(M>1)
      M--;
    else if (i == N)
      break;
    else
      i += 1;
  M+=1;
  Point tmp = H[M];
 H[M] = H[i];
 H[i] = tmp;
Point[] Hull = new Point[M];
for(int i = 0; i < M; i++)
 Hull[i] = H[i];
return Hull;
```

6. NP Tricks

}

6.1. **MaxClique.** The max clique problem is one of Karp's 21 NP-complete problems. The problem is to find the lagest subset of an undirected graph that forms a clique - a complete graph. There is an obvious algorithm that just inspects every subset of the graph and determines if this subset is a clique. This algorithm runns in $\mathcal{O}(n^2 2^n)$. However one can use the meet in the middle trick (one step divide and conqurer) and reduce the complexity to $\mathcal{O}(n^2 2^{\frac{n}{2}})$.

```
static int max_clique(int n, int[][] adj) {
   int fst = n/2;
   int snd = n - fst;
   int[] maxc = new int[1<<fst];
   int max = 1;
   for(int i = 0; i<(1<<fst); i++) {
      for(int a = 0; a<fst; a++) {
        if((i&1<<a) != 0)
            maxc[i] = Math.max(maxc[i], maxc[i^(1<<a)]);
      }
      boolean ok = true;</pre>
```

```
for(int a = 0; a<fst; a++) if((i&1<<a) != 0) {
      for(int b = a+1; b<fst; b++) {</pre>
          if((i\&1 << b) != 0 \&\& adj[a][b] == 0)
               ok = false;
      }
    if(ok) {
      maxc[i] = Integer.bitCount(i);
      max = Math.max(max, maxc[i]);
  for(int i = 0; i < (1 << snd); i++) {
    boolean ok = true:
    for(int a = 0; a<snd; a++) if((i\&1<<a) != 0) {
      for(int b = a+1; b<snd; b++) {</pre>
        if((i\&1 << b) != 0)
          if(adj[a+fst][b+fst] == 0)
             ok = false:
      }
    if(!ok) continue;
    int mask = 0;
    for(int a = 0; a<fst; a++) {</pre>
      ok = true;
      for(int b = 0; b < snd; b++) {
        if((i&1<<b) != 0) {
          if(adj[a][b+fst] == 0) ok = false;
        }
      if(ok) mask |= (1 << a);
    max = Math.max(Integer.bitCount(i) + maxc[mask],
             max);
  return max;
}
```

7. Coordinate Geometry

7.1. **Area of a nonintersecting polygon.** The signed area of a polygon with n vertices is given by

$$A = \frac{1}{2} \sum_{i=0}^{n-1} (x_i y_{i+1} - x_{i+1} y_i)$$

7.2. **Intersection of two lines.** Two lines defined by

$$a_1x + b_1y + c_1 = 0$$
$$a_2x + b_2y + c_2 = 0$$

Intersects in the point

$$P = (\frac{b_1c_2 - b_2c_1}{w}, \frac{a_2c_1 - a_1c_2}{w}),$$

where $w = a_1b_2 - a_2b_1$. If w = 0 the lines are parallell.

7.3. Distance between line segment and point. Given a linesegment between point P, Q, the distance D to point R is given by:

$$a = Q_y - P_y$$

$$b = Q_x - P_x$$

$$c = P_x Q_y - P_y Q_x$$

$$R_P = (\frac{b(bR_x - aR_y) - ac}{a^2 + b^2}, \frac{a(aR_y - bR_x) - bc}{a^2 + b^2})$$

$$D = \begin{cases} \frac{|aR_x + bR_y + c|}{\sqrt{a^2 + b^2}} & \text{if } (R_{P_x} - P_x)(R_{P_x} - Q_x) < 0, \\ \min |P - R|, |Q - R| & \text{otherwise} \end{cases}$$

$$a, b, c = 1$$

$$return ((b*(b*p[0] - can be proved by a point of the distance by a point of the distance be proved by a$$

7.4. Implementations.

import math

Distance between two points

```
def dist(p, q):

return math.hypot(p[\theta]-q[\theta], p[1] - q[1])
```

Converts two points to a line (a, b, c), # ax + by + c = 0

if p == a, a = b = c = 0

def pts2line(p, q):

return (-q[1] + p[1], q[0] - p[0],

p[0]*q[1] - p[1]*q[0])

Distance from a point to a line,

given that a != 0 or b != 0

def distl(l, p):
 return (abs(l[0]*p[0] + l[1]*p[1] + l[2])
